O'REILLY®

Elasticsearch The Definitive Guide

A DISTRIBUTED REAL-TIME SEARCH AND ANALYTICS ENGINE

Clinton Gormley & Zachary Tong

O'Reilly Ebooks—Your bookshelf on your devices!

When you buy an ebook through <u>oreilly.com</u> you get lifetime access to the book, and whenever possible we provide it to you in five, DRM-free file formats—PDF, .epub, Kindle-compatible .mobi, Android .apk, and DAISY—that you can use on the devices of your choice. Our ebook files are fully searchable, and you can cut-and-paste and print them. We also alert you when we've updated the files with corrections and additions.

Learn more at ebooks.oreilly.com

You can also purchase O'Reilly ebooks through the iBookstore, the <u>Android Marketplace</u>, and <u>Amazon.com</u>.

Table of Contents

Foreword	ххі
Preface	xxiii
Part I. Getting Started	
1. You Know, for Search	3
Installing Elasticsearch	4
Installing Marvel	5
Running Elasticsearch	5
Viewing Marvel and Sense	6
Talking to Elasticsearch	6
Java API	6
RESTful API with JSON over HTTP	7
Document Oriented	9
JSON	9
Finding Your Feet	10
Let's Build an Employee Directory	10
Indexing Employee Documents	10
Retrieving a Document	12
Search Lite	13
Search with Query DSL	15
More-Complicated Searches	16
Full-Text Search	17
Phrase Search	18
Highlighting Our Searches	19
Analytics	20
Tutorial Conclusion	23

	Distributed Nature Next Steps	23 24
_	•	
2.	Life Inside a Cluster.	25
	An Empty Cluster	26
	Cluster Health	26
	Add an Index	27
	Add Failover	29
	Scale Horizontally	30
	Then Scale Some More	31
	Coping with Failure	32
3.	Data In, Data Out	35
	What Is a Document?	36
	Document Metadata	37
	_index	37
	_type	37
	_id	38
	Other Metadata	38
	Indexing a Document	38
	Using Our Own ID	38
	Autogenerating IDs	39
	Retrieving a Document	40
	Retrieving Part of a Document	41
	Checking Whether a Document Exists	42
	Updating a Whole Document	42
	Creating a New Document	43
	Deleting a Document	44
	Dealing with Conflicts	45
	Optimistic Concurrency Control	47
	Using Versions from an External System	49
	Partial Updates to Documents	50 51
	Using Scripts to Make Partial Updates Undeting a Dogument That May Not Yet Eviet	
	Updating a Document That May Not Yet Exist	52 52
	Updates and Conflicts Patrioving Multiple Documents	53 54
	Retrieving Multiple Documents	56
	Cheaper in Bulk Don't Repeat Yourself	60
	How Big Is Too Big?	60
	110M DIS 19 100 DIS:	υU
4.	Distributed Document Store	61
	Routing a Document to a Shard	61

	How Primary and Replica Shards Interact	62
	Creating, Indexing, and Deleting a Document	63
	Retrieving a Document	65
	Partial Updates to a Document	66
	Multidocument Patterns	67
	Why the Funny Format?	69
5.	Searching—The Basic Tools.	71
	The Empty Search	72
	hits	73
	took	73
	shards	73
	timeout	74
	Multi-index, Multitype	74
	Pagination	75
	Search Lite	76
	The _all Field	77
	More Complicated Queries	78
6.	Mapping and Analysis	79
	Exact Values Versus Full Text	80
	Inverted Index	81
	Analysis and Analyzers	84
	Built-in Analyzers	84
	When Analyzers Are Used	85
	Testing Analyzers	86
	Specifying Analyzers	87
	Mapping	87
	Core Simple Field Types	88
	Viewing the Mapping	89
	Customizing Field Mappings	89
	Updating a Mapping	91
	Testing the Mapping	92
	Complex Core Field Types	93
	Multivalue Fields	93
	Empty Fields	93
	Multilevel Objects	94 94
	Mapping for Inner Objects How Inner Objects are Indexed	94 95
	How Inner Objects are Indexed	95 95
	Arrays of Inner Objects	73

7.	Full-Body Search	97
	Empty Search	97
	Query DSL	98
	Structure of a Query Clause	99
	Combining Multiple Clauses	99
	Queries and Filters	100
	Performance Differences	101
	When to Use Which	101
	Most Important Queries and Filters	102
	term Filter	102
	terms Filter	102
	range Filter	102
	exists and missing Filters	103
	bool Filter	103
	match_all Query	103
	match Query	104
	multi_match Query	104
	bool Query	105
	Combining Queries with Filters	105
	Filtering a Query	106
	Just a Filter	107
	A Query as a Filter	107
	Validating Queries	108
	Understanding Errors	108
	Understanding Queries	109
8.	Sorting and Relevance	111
	Sorting	111
	Sorting by Field Values	112
	Multilevel Sorting	113
	Sorting on Multivalue Fields	113
	String Sorting and Multifields	114
	What Is Relevance?	115
	Understanding the Score	116
	Understanding Why a Document Matched	119
	Fielddata	119
9.	Distributed Search Execution	121
	Query Phase	122
	Fetch Phase	123
	Search Options	125
	preference	125

	timeout	126
	routing	126
	search_type	127
	scan and scroll	127
10.	Index Management	131
	Creating an Index	131
	Deleting an Index	132
	Index Settings	132
	Configuring Analyzers	133
	Custom Analyzers	134
	Creating a Custom Analyzer	135
	Types and Mappings	137
	How Lucene Sees Documents	137
	How Types Are Implemented	138
	Avoiding Type Gotchas	138
	The Root Object	140
	Properties	140
	Metadata: _source Field	141
	Metadata: _all Field	142
	Metadata: Document Identity	144
	Dynamic Mapping	145
	Customizing Dynamic Mapping	147
	date_detection	147
	dynamic_templates	148
	Default Mapping	149
	Reindexing Your Data	150
	Index Aliases and Zero Downtime	151
11.	Inside a Shard	153
	Making Text Searchable	154
	Immutability	155
	Dynamically Updatable Indices	155
	Deletes and Updates	158
	Near Real-Time Search	159
	refresh API	160
	Making Changes Persistent	161
	flush API	165
	Segment Merging	166

rartii. Seartii iii vepti	Part	II.	Search	in Depth
---------------------------	-------------	-----	--------	----------

12.	Structured Search	173
	Finding Exact Values	173
	term Filter with Numbers	174
	term Filter with Text	175
	Internal Filter Operation	178
	Combining Filters	179
	Bool Filter	179
	Nesting Boolean Filters	181
	Finding Multiple Exact Values	182
	Contains, but Does Not Equal	183
	Equals Exactly	184
	Ranges	185
	Ranges on Dates	186
	Ranges on Strings	187
	Dealing with Null Values	187
	exists Filter	188
	missing Filter	190
	exists/missing on Objects	191
	All About Caching	192
	Independent Filter Caching	192
	Controlling Caching	193
	Filter Order	194
13.	Full-Text Search.	197
	Term-Based Versus Full-Text	197
	The match Query	199
	Index Some Data	199
	A Single-Word Query	200
	Multiword Queries	201
	Improving Precision	202
	Controlling Precision	203
	Combining Queries	204
	Score Calculation	205
	Controlling Precision	205
	How match Uses bool	206
	Boosting Query Clauses	207
	Controlling Analysis	209

	Default Analyzers	211
	Configuring Analyzers in Practice	213
	Relevance Is Broken!	214
14.	Multifield Search	217
	Multiple Query Strings	217
	Prioritizing Clauses	218
	Single Query String	219
	Know Your Data	220
	Best Fields	221
	dis_max Query	222
	Tuning Best Fields Queries	223
	tie_breaker	224
	multi_match Query	225
	Using Wildcards in Field Names	226
	Boosting Individual Fields	227
	Most Fields	227
	Multifield Mapping	228
	Cross-fields Entity Search	231
	A Naive Approach	231
	Problems with the most_fields Approach	232
	Field-Centric Queries	232
	Problem 1: Matching the Same Word in Multiple Fields	233
	Problem 2: Trimming the Long Tail	233
	Problem 3: Term Frequencies	234
	Solution	235
	Custom _all Fields	235
	cross-fields Queries	236
	Per-Field Boosting	238
	Exact-Value Fields	239
15.	Proximity Matching	241
	Phrase Matching	242
	Term Positions	242
	What Is a Phrase	243
	Mixing It Up	244
	Multivalue Fields	245
	Closer Is Better	246
	Proximity for Relevance	247
	Improving Performance	249
	Rescoring Results	249
	Finding Associated Words	250

	Producing Shingles	251
	Multifields	252
	Searching for Shingles	253
	Performance	255
16.	Partial Matching	257
	Postcodes and Structured Data	258
	prefix Query	259
	wildcard and regexp Queries	260
	Query-Time Search-as-You-Type	262
	Index-Time Optimizations	264
	Ngrams for Partial Matching	264
	Index-Time Search-as-You-Type	265
	Preparing the Index	265
	Querying the Field	267
	Edge n-grams and Postcodes	270
	Ngrams for Compound Words	271
17.	Controlling Relevance	275
	Theory Behind Relevance Scoring	275
	Boolean Model	276
	Term Frequency/Inverse Document Frequency (TF/IDF)	276
	Vector Space Model	279
	Lucene's Practical Scoring Function	282
	Query Normalization Factor	283
	Query Coordination	284
	Index-Time Field-Level Boosting	286
	Query-Time Boosting	286
	Boosting an Index	287
	t.getBoost()	288
	Manipulating Relevance with Query Structure	288
	Not Quite Not	289
	boosting Query	290
	Ignoring TF/IDF	291
	constant_score Query	291
	function_score Query	293
	Boosting by Popularity	294
	modifier	296
	factor	298
	boost_mode	299
	max_boost	301
	Boosting Filtered Subsets	301

You Know, for Search...

Elasticsearch is an open-source search engine built on top of Apache Lucene™, a full-text search-engine library. Lucene is arguably the most advanced, high-performance, and fully featured search engine library in existence today—both open source and proprietary.

But Lucene is just a library. To leverage its power, you need to work in Java and to integrate Lucene directly with your application. Worse, you will likely require a degree in information retrieval to understand how it works. Lucene is *very* complex.

Elasticsearch is also written in Java and uses Lucene internally for all of its indexing and searching, but it aims to make full-text search easy by hiding the complexities of Lucene behind a simple, coherent, RESTful API.

However, Elasticsearch is much more than just Lucene and much more than "just" full-text search. It can also be described as follows:

- A distributed real-time document store where every field is indexed and searchable
- A distributed search engine with real-time analytics
- Capable of scaling to hundreds of servers and petabytes of structured and unstructured data

And it packages up all this functionality into a standalone server that your application can talk to via a simple RESTful API, using a web client from your favorite programming language, or even from the command line.

It is easy to get started with Elasticsearch. It ships with sensible defaults and hides complicated search theory away from beginners. It *just works*, right out of the box. With minimal understanding, you can soon become productive.

Elasticsearch can be downloaded, used, and modified free of charge. It is available under the Apache 2 license, one of the most flexible open source licenses available.

As your knowledge grows, you can leverage more of Elasticsearch's advanced features. The entire engine is configurable and flexible. Pick and choose from the advanced features to tailor Elasticsearch to your problem domain.

The Mists of Time

Many years ago, a newly married unemployed developer called Shay Banon followed his wife to London, where she was studying to be a chef. While looking for gainful employment, he started playing with an early version of Lucene, with the intent of building his wife a recipe search engine.

Working directly with Lucene can be tricky, so Shay started work on an abstraction layer to make it easier for Java programmers to add search to their applications. He released this as his first open source project, called Compass.

Later Shay took a job working in a high-performance, distributed environment with in-memory data grids. The need for a high-performance, real-time, distributed search engine was obvious, and he decided to rewrite the Compass libraries as a standalone server called Elasticsearch.

The first public release came out in February 2010. Since then, Elasticsearch has become one of the most popular projects on GitHub with commits from over 300 contributors. A company has formed around Elasticsearch to provide commercial support and to develop new features, but Elasticsearch is, and forever will be, open source and available to all.

Shay's wife is still waiting for the recipe search...

Installing Elasticsearch

The easiest way to understand what Elasticsearch can do for you is to play with it, so let's get started!

The only requirement for installing Elasticsearch is a recent version of Java. Preferably, you should install the latest version of the official Java from www.java.com.

You can download the latest version of Elasticsearch from *elasticsearch.org/download*.

```
curl -L -O http://download.elasticsearch.org/PATH/TO/VERSION.zip unzip elasticsearch-$VERSION.zip cd elasticsearch-$VERSION
```

• Fill in the URL for the latest version available on *elasticsearch.org/download*.

When installing Elasticsearch in production, you can use the method described previously, or the Debian or RPM packages provided on the downloads page. You can also use the officially supported Puppet module or Chef cookbook.

Installing Marvel

Marvel is a management and monitoring tool for Elasticsearch, which is free for development use. It comes with an interactive console called Sense, which makes it easy to talk to Elasticsearch directly from your browser.

Many of the code examples in the online version of this book include a View in Sense link. When clicked, it will open up a working example of the code in the Sense console. You do not have to install Marvel, but it will make this book much more interactive by allowing you to experiment with the code samples on your local Elasticsearch cluster.

Marvel is available as a plug-in. To download and install it, run this command in the Elasticsearch directory:

```
./bin/plugin -i elasticsearch/marvel/latest
```

You probably don't want Marvel to monitor your local cluster, so you can disable data collection with this command:

```
echo 'marvel.agent.enabled: false' >> ./config/elasticsearch.yml
```

Running Elasticsearch

Elasticsearch is now ready to run. You can start it up in the foreground with this:

```
./bin/elasticsearch
```

Add -d if you want to run it in the background as a daemon.

Test it out by opening another terminal window and running the following:

```
curl 'http://localhost:9200/?pretty'
```

You should see a response like this:

```
"status": 200,
   "name": "Shrunken Bones",
   "version": {
      "number": "1.4.0",
      "lucene_version": "4.10"
   'tagline": "You Know, for Search"
}
```

This means that your Elasticsearch *cluster* is up and running, and we can start experimenting with it.

A node is a running instance of Elasticsearch. A cluster is a group of nodes with the same cluster.name that are working together to share data and to provide failover and scale, although a single node can form a cluster all by itself.

You should change the default cluster.name to something appropriate to you, like your own name, to stop your nodes from trying to join another cluster on the same network with the same name!

You can do this by editing the elasticsearch.yml file in the config/ directory and then restarting Elasticsearch. When Elasticsearch is running in the foreground, you can stop it by pressing Ctrl-C; otherwise, you can shut it down with the shutdown API:

curl -XPOST 'http://localhost:9200/_shutdown'

Viewing Marvel and Sense

If you installed the Marvel management and monitoring tool, you can view it in a web browser by visiting http://localhost:9200/_plugin/marvel/.

You can reach the Sense developer console either by clicking the "Marvel dashboards" drop-down in Marvel, or by visiting http://localhost:9200/ plugin/marvel/sense/.

Talking to Elasticsearch

How you talk to Elasticsearch depends on whether you are using Java.

Java API

If you are using Java, Elasticsearch comes with two built-in clients that you can use in your code:

Node client

The node client joins a local cluster as a non data node. In other words, it doesn't hold any data itself, but it knows what data lives on which node in the cluster, and can forward requests directly to the correct node.

Transport client

The lighter-weight transport client can be used to send requests to a remote cluster. It doesn't join the cluster itself, but simply forwards requests to a node in the cluster.

Both Java clients talk to the cluster over port 9300, using the native Elasticsearch transport protocol. The nodes in the cluster also communicate with each other over port 9300. If this port is not open, your nodes will not be able to form a cluster.

The Java client must be from the same version of Elasticsearch as the nodes; otherwise, they may not be able to understand each

More information about the Java clients can be found in the Java API section of the Guide.

RESTful API with JSON over HTTP

All other languages can communicate with Elasticsearch over port 9200 using a RESTful API, accessible with your favorite web client. In fact, as you have seen, you can even talk to Elasticsearch from the command line by using the curl command.

Elasticsearch provides official clients for several languages— Groovy, JavaScript, .NET, PHP, Perl, Python, and Ruby-and there are numerous community-provided clients and integrations, all of which can be found in the Guide.

A request to Elasticsearch consists of the same parts as any HTTP request:

```
curl -X<VERB> '<PROTOCOL>://<HOST>/<PATH>?<QUERY_STRING>' -d '<BODY>'
```

The parts marked with < > above are:

VERB

The appropriate HTTP *method* or *verb*: GET, POST, PUT, HEAD, or DELETE.

PROTOCOL

Either http or https (if you have an https proxy in front of Elasticsearch.)

HOST

The hostname of any node in your Elasticsearch cluster, or localhost for a node on your local machine.

PORT

The port running the Elasticsearch HTTP service, which defaults to 9200.

QUERY STRING

Any optional query-string parameters (for example ?pretty will pretty-print the JSON response to make it easier to read.)

A JSON-encoded request body (if the request needs one.)

For instance, to count the number of documents in the cluster, we could use this:

```
curl -XGET 'http://localhost:9200/_count?pretty' -d '
{
    "query": {
        "match_all": {}
    }
}
```

Elasticsearch returns an HTTP status code like 200 OK and (except for HEAD requests) a JSON-encoded response body. The preceding curl request would respond with a JSON body like the following:

```
{
    "count" : 0,
    "_shards" : {
        "total" : 5,
        "successful" : 5,
        "failed" : 0
    }
}
```

We don't see the HTTP headers in the response because we didn't ask curl to display them. To see the headers, use the curl command with the -i switch:

```
curl -i -XGET 'localhost:9200/'
```

For the rest of the book, we will show these curl examples using a shorthand format that leaves out all the bits that are the same in every request, like the hostname and port, and the curl command itself. Instead of showing a full request like

```
curl -XGET 'localhost:9200/_count?pretty' -d '
{
    "query": {
        "match_all": {}
    }
}'
```

we will show it in this shorthand format:

```
GET /_count
{
     "query": {
          "match_all": {}
     }
}
```

In fact, this is the same format that is used by the Sense console that we installed with Marvel. If in the online version of this book, you can open and run this code example in Sense by clicking the View in Sense link above.

Document Oriented

Objects in an application are seldom just a simple list of keys and values. More often than not, they are complex data structures that may contain dates, geo locations, other objects, or arrays of values.

Sooner or later you're going to want to store these objects in a database. Trying to do this with the rows and columns of a relational database is the equivalent of trying to squeeze your rich, expressive objects into a very big spreadsheet: you have to flatten the object to fit the table schema—usually one field per column—and then have to reconstruct it every time you retrieve it.

Elasticsearch is document oriented, meaning that it stores entire objects or documents. It not only stores them, but also indexes the contents of each document in order to make them searchable. In Elasticsearch, you index, search, sort, and filter documents —not rows of columnar data. This is a fundamentally different way of thinking about data and is one of the reasons Elasticsearch can perform complex full-text search.

JSON

Elasticsearch uses JavaScript Object Notation, or ISON, as the serialization format for documents. JSON serialization is supported by most programming languages, and has become the standard format used by the NoSQL movement. It is simple, concise, and easy to read.

Consider this JSON document, which represents a user object:

```
"email": "john@smith.com",
"first name": "John",
"last name": "Smith",
"info": {
   "bio":
                 "Eco-warrior and defender of the weak",
   "age": 25,
   "interests": [ "dolphins", "whales" ]
"join_date": "2014/05/01"
```

Although the original user object was complex, the structure and meaning of the object has been retained in the JSON version. Converting an object to JSON for indexing in Elasticsearch is much simpler than the equivalent process for a flat table structure.

Almost all languages have modules that will convert arbitrary data structures or objects into JSON for you, but the details are specific to each language. Look for modules that handle JSON serialization or marshalling. The official Elasticsearch clients all handle conversion to and from JSON for you automatically.

Finding Your Feet

To give you a feel for what is possible in Elasticsearch and how easy it is to use, let's start by walking through a simple tutorial that covers basic concepts such as indexing, search, and aggregations.

We'll introduce some new terminology and basic concepts along the way, but it is OK if you don't understand everything immediately. We'll cover all the concepts introduced here in *much* greater depth throughout the rest of the book.

So, sit back and enjoy a whirlwind tour of what Elasticsearch is capable of.

Let's Build an Employee Directory

We happen to work for *Megacorp*, and as part of HR's new "We love our drones!" initiative, we have been tasked with creating an employee directory. The directory is supposed to foster employer empathy and real-time, synergistic, dynamic collaboration, so it has a few business requirements:

- Enable data to contain multi value tags, numbers, and full text.
- Retrieve the full details of any employee.
- Allow structured search, such as finding employees over the age of 30.
- Allow simple full-text search and more-complex *phrase* searches.
- Return highlighted search *snippets* from the text in the matching documents.
- Enable management to build analytic dashboards over the data.

Indexing Employee Documents

The first order of business is storing employee data. This will take the form of an employee document': a single document represents a single employee. The act of storing data in Elasticsearch is called *indexing*, but before we can index a document, we need to decide where to store it.

In Elasticsearch, a document belongs to a *type*, and those types live inside an *index*. You can draw some (rough) parallels to a traditional relational database:

```
Relational DB \Rightarrow Databases \Rightarrow Tables \Rightarrow Rows
                                                           ⇒ Columns
Elasticsearch ⇒ Indices ⇒ Types ⇒ Documents ⇒ Fields
```

An Elasticsearch cluster can contain multiple indices (databases), which in turn contain multiple types (tables). These types hold multiple documents (rows), and each document has multiple *fields* (columns).

Index Versus Index Versus Index

You may already have noticed that the word index is overloaded with several meanings in the context of Elasticsearch. A little clarification is necessary:

Index (noun)

As explained previously, an index is like a database in a traditional relational database. It is the place to store related documents. The plural of *index* is *indices* or indexes.

Index (verb)

To index a document is to store a document in an index (noun) so that it can be retrieved and queried. It is much like the INSERT keyword in SQL except that, if the document already exists, the new document would replace the old.

Inverted index

Relational databases add an index, such as a B-tree index, to specific columns in order to improve the speed of data retrieval. Elasticsearch and Lucene use a structure called an *inverted index* for exactly the same purpose.

By default, every field in a document is indexed (has an inverted index) and thus is searchable. A field without an inverted index is not searchable. We discuss inverted indexes in more detail in "Inverted Index" on page 81.

So for our employee directory, we are going to do the following:

- Index a document per employee, which contains all the details of a single employee.
- Each document will be of *type* employee.
- That type will live in the megacorp *index*.
- That index will reside within our Elasticsearch cluster.

In practice, this is easy (even though it looks like a lot of steps). We can perform all of those actions in a single command:

```
PUT /megacorp/employee/1
    "first_name" : "John",
    "last_name" : "Smith",
```

```
"age" : 25,
"about" : "I love to go rock climbing",
    "interests": [ "sports", "music" ]
}
```

Notice that the path /megacorp/employee/1 contains three pieces of information:

```
megacorp
    The index name
employee
    The type name
1
    The ID of this particular employee
```

The request body—the JSON document—contains all the information about this employee. His name is John Smith, he's 25, and enjoys rock climbing.

Simple! There was no need to perform any administrative tasks first, like creating an index or specifying the type of data that each field contains. We could just index a document directly. Elasticsearch ships with defaults for everything, so all the necessary administration tasks were taken care of in the background, using default values.

Before moving on, let's add a few more employees to the directory:

```
PUT /megacorp/employee/2
{
    "first name" : "Jane".
    "last_name" : "Smith",
    "age": 32,
"about": "I like to collect rock albums",
    "interests": [ "music" ]
}
PUT /megacorp/employee/3
    "first_name" : "Douglas",
    "last_name" : "Fir",
    "age" : 35,
"about": "I like to build cabinets",
    "interests": [ "forestry" ]
}
```

Retrieving a Document

Now that we have some data stored in Elasticsearch, we can get to work on the business requirements for this application. The first requirement is the ability to retrieve individual employee data.

This is easy in Elasticsearch. We simply execute an HTTP GET request and specify the address of the document—the index, type, and ID. Using those three pieces of information, we can return the original JSON document:

```
GET /megacorp/employee/1
```

And the response contains some metadata about the document, and John Smith's original JSON document as the source field:

```
"_index" :
               "megacorp",
  "_type" :
               "employee".
  " id" :
               "1".
 "_version" : 1,
  "found":
  " source" : {
      "first_name" : "John",
      "last_name" :
                     "Smith",
      "age" :
                     25,
                    "I love to go rock climbing",
      "about" :
      "interests": [ "sports", "music" ]
 }
}
```

In the same way that we changed the HTTP verb from PUT to GET in order to retrieve the document, we could use the DELETE verb to delete the document, and the HEAD verb to check whether the document exists. To replace an existing document with an updated version, we just PUT it again.

Search Lite

A GET is fairly simple—you get back the document that you ask for. Let's try something a little more advanced, like a simple search!

The first search we will try is the simplest search possible. We will search for all employees, with this request:

```
GET /megacorp/employee/_search
```

You can see that we're still using index megacorp and type employee, but instead of specifying a document ID, we now use the _search endpoint. The response includes all three of our documents in the hits array. By default, a search will return the top 10 results.

```
"took":
             6,
"timed out": false.
"_shards": { ... },
"hits": {
```

```
"total":
                    3.
      "max_score": 1,
      "hits": [
         {
            "_index":
                               "megacorp",
            _
"_type":
                               "employee",
            "_id":
                               "3",
            "_score":
            "_source": {
                               "Douglas",
               "first_name":
               "last_name":
                               "Fir",
               "age":
                               35,
               "about":
                               "I like to build cabinets",
               "interests": [ "forestry" ]
            }
         },
            "_index":
                               "megacorp",
            "_type":
                               "employee",
            "_id":
                               "1",
            "_score":
            "_source": {
               "first_name":
                               "John",
               "last_name":
                               "Smith",
               "age":
                               25,
                               "I love to go rock climbing",
               "about":
               "interests": [ "sports", "music" ]
            }
         },
            "_index":
                               "megacorp",
            "_type":
                               "employee",
            "_id":
                               "2",
            "_score":
            "_source": {
               "first_name":
                               "Jane",
               "last_name":
                               "Smith",
               "age":
                               32,
               "about":
                               "I like to collect rock albums",
               "interests": [ "music" ]
            }
         }
      ]
  }
}
```

The response not only tells us which documents matched, but also includes the whole document itself: all the information that we need in order to display the search results to the user.

Next, let's try searching for employees who have "Smith" in their last name. To do this, we'll use a *lightweight* search method that is easy to use from the command line. This method is often referred to as a *query-string* search, since we pass the search as a URL query-string parameter:

```
GET /megacorp/employee/_search?q=last_name:Smith
```

We use the same _search endpoint in the path, and we add the query itself in the q= parameter. The results that come back show all Smiths:

```
{
  "hits": {
     "total":
                  2,
     "max score": 0.30685282,
     "hits": [
        {
           "_source": {
              "first name": "John",
              "last_name": "Smith",
              "about": "I love to go rock climbing",
              "interests": [ "sports", "music" ]
           }
        },
           "_source": {
              "first name": "Jane",
              "last_name":
                            "Smith".
              "age":
                            32,
              "about":
                       "I like to collect rock albums",
              "interests": [ "music" ]
           }
        }
     ]
  }
}
```

Search with Query DSL

Query-string search is handy for ad hoc searches from the command line, but it has its limitations (see "Search Lite" on page 76). Elasticsearch provides a rich, flexible, query language called the query DSL, which allows us to build much more complicated, robust queries.

The domain-specific language (DSL) is specified using a JSON request body. We can represent the previous search for all Smiths like so:

```
GET /megacorp/employee/_search
    "query" : {
        "match" : {
            "last_name" : "Smith"
    }
}
```

This will return the same results as the previous query. You can see that a number of things have changed. For one, we are no longer using query-string parameters, but instead a request body. This request body is built with JSON, and uses a match query (one of several types of queries, which we will learn about later).

More-Complicated Searches

Let's make the search a little more complicated. We still want to find all employees with a last name of Smith, but we want only employees who are older than 30. Our query will change a little to accommodate a filter, which allows us to execute structured searches efficiently:

```
GET /megacorp/employee/_search
{
    "query" : {
        "filtered" : {
            "filter" : {
                "range" : {
                    "age" : { "gt" : 30 } ①
            },
            "query" : {
                "match" : {
                    "last name" : "smith" 2
            }
        }
    }
}
```

- This portion of the query is a range *filter*, which will find all ages older than 30 gt stands for greater than.
- This portion of the query is the same match *query* that we used before.

Don't worry about the syntax too much for now; we will cover it in great detail later. Just recognize that we've added a *filter* that performs a range search, and reused the same match query as before. Now our results show only one employee who happens to be 32 and is named Jane Smith:

```
{
  "hits": {
     "total":
                  1,
     "max score": 0.30685282,
     "hits": [
        {
           "_source": {
              "first_name": "Jane",
              "last_name":
                            "Smith".
              "age":
                             32,
              "about": "I like to collect rock albums",
              "interests": [ "music" ]
        }
     ]
  }
```

Full-Text Search

The searches so far have been simple: single names, filtered by age. Let's try a more advanced, full-text search—a task that traditional databases would really struggle with.

We are going to search for all employees who enjoy rock climbing:

```
GET /megacorp/employee/_search
    "query" : {
        "match" : {
            "about" : "rock climbing"
        }
    }
}
```

You can see that we use the same match query as before to search the about field for "rock climbing." We get back two matching documents:

```
{
   "hits": {
      "total":
                   2,
      "max_score": 0.16273327,
      "hits": [
         {
            "_score":
                              0.16273327, 1
             source": {
               "first_name":
                             "John",
               "last name":
                              "Smith",
```

```
"age":
                              25.
               "about":
                              "I love to go rock climbing",
               "interests": [ "sports", "music" ]
            }
         },
            " score":
                              0.016878016.
             _source": {
                             "Jane",
               "first name":
               "last name":
                              "Smith",
               "age":
                              32,
               "about":
                              "I like to collect rock albums",
               "interests": [ "music" ]
            }
        }
      1
  }
}
```

The relevance scores

By default, Elasticsearch sorts matching results by their relevance score, that is, by how well each document matches the query. The first and highest-scoring result is obvious: John Smith's about field clearly says "rock climbing" in it.

But why did Jane Smith come back as a result? The reason her document was returned is because the word "rock" was mentioned in her about field. Because only "rock" was mentioned, and not "climbing," her _score is lower than John's.

This is a good example of how Elasticsearch can search within full-text fields and return the most relevant results first. This concept of relevance is important to Elasticsearch, and is a concept that is completely foreign to traditional relational databases, in which a record either matches or it doesn't.

Phrase Search

Finding individual words in a field is all well and good, but sometimes you want to match exact sequences of words or phrases. For instance, we could perform a query that will match only employee records that contain both "rock" and "climbing" and that display the words are next to each other in the phrase "rock climbing."

To do this, we use a slight variation of the match query called the match_phrase query:

```
GET /megacorp/employee/_search
    "query" : {
        "match_phrase" : {
```

```
"about" : "rock climbing"
        }
    }
}
```

This, to no surprise, returns only John Smith's document:

```
{
   "hits": {
      "total":
      "max score": 0.23013961,
      "hits": [
         {
            "_score":
                              0.23013961,
             _source": {
                              "John",
               "first_name":
               "last_name":
                              "Smith",
               "age":
                              25,
               "about":
                              "I love to go rock climbing",
               "interests": [ "sports", "music" ]
            }
         }
      ]
  }
}
```

Highlighting Our Searches

Many applications like to *highlight* snippets of text from each search result so the user can see why the document matched the query. Retrieving highlighted fragments is easy in Elasticsearch.

Let's rerun our previous query, but add a new highlight parameter:

```
GET /megacorp/employee/_search
{
    "query" : {
        "match_phrase" : {
            "about" : "rock climbing"
        }
    },
    "highlight": {
        "fields" : {
            "about" : {}
        }
    }
}
```

When we run this query, the same hit is returned as before, but now we get a new section in the response called highlight. This contains a snippet of text from the about field with the matching words wrapped in HTML tags:

```
{
   "hits": {
     "total":
                 1,
      "max score": 0.23013961,
      "hits": [
        {
            "_score":
                            0.23013961.
            " source": {
              "first_name": "John",
               "last name": "Smith",
              "age":
"about":
                           "I love to go rock climbing",
               "interests": [ "sports", "music" ]
            "highlight": {
               "about": [
                  "I love to go <em>rock</em> <em>climbing</em>" 1
           }
        }
     1
  }
}
```

The highlighted fragment from the original text

You can read more about the highlighting of search snippets in the highlighting reference documentation.

Analytics

Finally, we come to our last business requirement: allow managers to run analytics over the employee directory. Elasticsearch has functionality called aggregations, which allow you to generate sophisticated analytics over your data. It is similar to GROUP BY in SQL, but much more powerful.

For example, let's find the most popular interests enjoyed by our employees:

```
GET /megacorp/employee/ search
 "aggs": {
   "all interests": {
     "terms": { "field": "interests" }
   }
```

```
}
```

Ignore the syntax for now and just look at the results:

```
{
   "hits": { ... },
   "aggregations": {
      "all_interests": {
         "buckets": [
            {
                "key":
                              "music".
                "doc_count": 2
            },
                "key":
                              "forestry",
                "doc_count": 1
            },
                "key":
                              "sports",
                "doc_count": 1
            }
         ]
      }
   }
}
```

We can see that two employees are interested in music, one in forestry, and one in sports. These aggregations are not precalculated; they are generated on the fly from the documents that match the current query. If we want to know the popular interests of people called Smith, we can just add the appropriate query into the mix:

```
GET /megacorp/employee/ search
  "query": {
    "match": {
      "last_name": "smith"
    }
 },
  "aggs": {
    "all_interests": {
      "terms": {
        "field": "interests"
      }
   }
  }
```

The all_interests aggregation has changed to include only documents matching our query:

```
"all_interests": {
   "buckets": [
      {
         "key": "music",
         "doc_count": 2
      },
         "key": "sports",
         "doc_count": 1
      }
   ]
}
```

Aggregations allow hierarchical rollups too. For example, let's find the average age of employees who share a particular interest:

```
GET /megacorp/employee/ search
    "aggs" : {
        "all_interests" : {
            "terms" : { "field" : "interests" },
            "aggs" : {
                "avg_age" : {
                    "avg" : { "field" : "age" }
            }
        }
    }
}
```

The aggregations that we get back are a bit more complicated, but still fairly easy to understand:

```
"all_interests": {
   "buckets": [
      {
         "key": "music",
         "doc_count": 2,
         "avg_age": {
            "value": 28.5
      },
         "key": "forestry",
         "doc_count": 1,
         "avg_age": {
            "value": 35
      },
         "key": "sports",
```

```
"doc_count": 1,
         "avg_age": {
             "value": 25
      }
   ]
}
```

The output is basically an enriched version of the first aggregation we ran. We still have a list of interests and their counts, but now each interest has an additional avg_age, which shows the average age for all employees having that interest.

Even if you don't understand the syntax yet, you can easily see how complex aggregations and groupings can be accomplished using this feature. The sky is the limit as to what kind of data you can extract!

Tutorial Conclusion

Hopefully, this little tutorial was a good demonstration about what is possible in Elasticsearch. It is really just scratching the surface, and many features—such as suggestions, geolocation, percolation, fuzzy and partial matching—were omitted to keep the tutorial short. But it did highlight just how easy it is to start building advanced search functionality. No configuration was needed—just add data and start searching!

It's likely that the syntax left you confused in places, and you may have questions about how to tweak and tune various aspects. That's fine! The rest of the book dives into each of these issues in detail, giving you a solid understanding of how Elasticsearch works.

Distributed Nature

At the beginning of this chapter, we said that Elasticsearch can scale out to hundreds (or even thousands) of servers and handle petabytes of data. While our tutorial gave examples of how to use Elasticsearch, it didn't touch on the mechanics at all. Elasticsearch is distributed by nature, and it is designed to hide the complexity that comes with being distributed.

The distributed aspect of Elasticsearch is largely transparent. Nothing in the tutorial required you to know about distributed systems, sharding, cluster discovery, or dozens of other distributed concepts. It happily ran the tutorial on a single node living inside your laptop, but if you were to run the tutorial on a cluster containing 100 nodes, everything would work in exactly the same way.

Elasticsearch tries hard to hide the complexity of distributed systems. Here are some of the operations happening automatically under the hood:

- Partitioning your documents into different containers or *shards*, which can be stored on a single node or on multiple nodes
- Balancing these shards across the nodes in your cluster to spread the indexing and search load
- Duplicating each shard to provide redundant copies of your data, to prevent data loss in case of hardware failure
- Routing requests from any node in the cluster to the nodes that hold the data you're interested in
- Seamlessly integrating new nodes as your cluster grows or redistributing shards to recover from node loss

As you read through this book, you'll encounter supplemental chapters about the distributed nature of Elasticsearch. These chapters will teach you about how the cluster scales and deals with failover (Chapter 2), handles document storage (Chapter 4), executes distributed search (Chapter 9), and what a shard is and how it works (Chapter 11).

These chapters are not required reading—you can use Elasticsearch without understanding these internals—but they will provide insight that will make your knowledge of Elasticsearch more complete. Feel free to skim them and revisit at a later point when you need a more complete understanding.

Next Steps

By now you should have a taste of what you can do with Elasticsearch, and how easy it is to get started. Elasticsearch tries hard to work out of the box with minimal knowledge and configuration. The best way to learn Elasticsearch is by jumping in: just start indexing and searching!

However, the more you know about Elasticsearch, the more productive you can become. The more you can tell Elasticsearch about the domain-specific elements of your application, the more you can fine-tune the output.

The rest of this book will help you move from novice to expert. Each chapter explains the essentials, but also includes expert-level tips. If you're just getting started, these tips are probably not immediately relevant to you; Elasticsearch has sensible defaults and will generally do the right thing without any interference. You can always revisit these chapters later, when you are looking to improve performance by shaving off any wasted milliseconds.
